

COL9A2 gene

collagen type IX alpha 2 chain

Normal Function

The *COL9A2* gene provides instructions for making part of a large molecule called type IX collagen. Collagens are a family of proteins that strengthen and support connective tissues, such as skin, bone, cartilage, tendons, and ligaments. In particular, type IX collagen is an important component of cartilage, which is a tough, flexible tissue that makes up much of the skeleton during early development. Most cartilage is later converted to bone, except for the cartilage that continues to cover and protect the ends of bones and is present in the nose and external ears.

Type IX collagen is made up of three proteins that are produced from three distinct genes: one $\alpha 1$ (IX) chain, which is produced from the *COL9A1* gene, one $\alpha 2$ (IX) chain, which is produced from the *COL9A2* gene, and one $\alpha 3$ (IX) chain, which is produced from the *COL9A3* gene. Type IX collagen is more flexible than other types of collagen molecules and is closely associated with type II collagen. Researchers believe that the flexible nature of type IX collagen allows it to act as a bridge that connects type II collagen with other cartilage components. Studies have shown that type IX collagen also interacts with the proteins produced from the *MATN3* and *COMP* genes.

Health Conditions Related to Genetic Changes

Multiple epiphyseal dysplasia

At least five mutations in the *COL9A2* gene have been shown to cause dominant multiple epiphyseal dysplasia, a disorder of cartilage and bone development that primarily affects the ends of the long bones in the arms and legs (epiphyses). All of these mutations disrupt how genetic information is spliced together to make the blueprint for producing the $\alpha 2$ (IX) chain. These mutations, called splice-site mutations, change one DNA building block (nucleotide) near an area of the gene called exon 3. These mutations in the *COL9A2* gene result in the deletion of 12 protein building blocks (amino acids) from the $\alpha 2$ (IX) chain. It is not known how mutations in *COL9A2* cause the signs and symptoms of dominant multiple epiphyseal dysplasia.

Stickler syndrome

Intervertebral disc disease

Chromosomal Location

Cytogenetic Location: 1p34.2, which is the short (p) arm of chromosome 1 at position 34.2

Molecular Location: base pairs 40,300,487 to 40,317,653 on chromosome 1 (Homo sapiens Annotation Release 109, GRCh38.p12) (NCBI)

Credit: Genome Decoration Page/NCBI

Other Names for This Gene
