

COL9A3 gene

collagen type IX alpha 3 chain

Normal Function

The *COL9A3* gene provides instructions for making part of a large molecule called type IX collagen. Collagens are a family of proteins that strengthen and support connective tissues, such as skin, bone, cartilage, tendons, and ligaments. In particular, type IX collagen is an important component of cartilage.

Type IX collagen is made up of three proteins that are produced from three distinct genes: one $\alpha 1$ (IX) chain, which is produced from the *COL9A1* gene, one $\alpha 2$ (IX) chain, which is produced from the *COL9A2* gene, and one $\alpha 3$ (IX) chain, which is produced from the *COL9A3* gene. Type IX collagen is more flexible than other types of collagen molecules and is closely associated with type II collagen. Researchers believe that the flexible nature of type IX collagen allows it to act as a bridge that connects type II collagen with other cartilage components. Studies have shown that type IX collagen also interacts with the proteins produced from the *MATN3* and *COMP* genes.

Health Conditions Related to Genetic Changes

Multiple epiphyseal dysplasia

At least three mutations in the *COL9A3* gene have been shown to cause dominant multiple epiphyseal dysplasia. All of these mutations disrupt how genetic information is spliced together to make the blueprint for producing the $\alpha 3$ (IX) chain. These mutations, called splice-site mutations, change one DNA building block (nucleotide) near an area of the gene called exon 3. These mutations in the *COL9A3* gene result in the deletion of 12 protein building blocks (amino acids) from the $\alpha 3$ (IX) chain. It is not known how mutations in *COL9A3* cause the signs and symptoms of dominant multiple epiphyseal dysplasia.

All identified mutations in type IX collagen delete a portion of the COL3 domain, which suggests that this region has an important function. Mutations may affect the ability of type IX collagen to fold correctly or interact with other cartilage components.

Intervertebral disc disease

Stickler syndrome

Chromosomal Location

Cytogenetic Location: 20q13.33, which is the long (q) arm of chromosome 20 at position 13.33

Molecular Location: base pairs 62,817,062 to 62,841,159 on chromosome 20 (Homo sapiens Annotation Release 109, GRCh38.p12) (NCBI)

Credit: Genome Decoration Page/NCBI
