HLA-DPB1 gene
major histocompatibility complex, class II, DP beta 1

Normal Function
The HLA-DPB1 gene provides instructions for making a protein that plays a critical role in the immune system. The HLA-DPB1 gene is part of a family of genes called the human leukocyte antigen (HLA) complex. The HLA complex helps the immune system distinguish the body’s own proteins from proteins made by foreign invaders such as viruses and bacteria.

The HLA complex is the human version of the major histocompatibility complex (MHC), a gene family that occurs in many species. The HLA-DPB1 gene belongs to a group of MHC genes called MHC class II. MHC class II genes provide instructions for making proteins that are present on the surface of certain immune system cells. These proteins attach to protein fragments (peptides) outside the cell. MHC class II proteins display these peptides to the immune system. If the immune system recognizes the peptides as foreign (such as viral or bacterial peptides), it triggers a response to attack the invading viruses or bacteria.

The protein produced from the HLA-DPB1 gene attaches (binds) to the protein produced from another MHC class II gene, HLA-DPA1. Together, they form a functional protein complex called an antigen-binding DPαβ heterodimer. This complex displays foreign peptides to the immune system to trigger the body’s immune response.

Each MHC class II gene has many possible variations, allowing the immune system to react to a wide range of foreign invaders. Researchers have identified hundreds of different versions (alleles) of the HLA-DPB1 gene, each of which is given a particular number (such as HLA-DPB1*03:01).

Health Conditions Related to Genetic Changes

Granulomatosis with polyangiitis
At least one variant of the HLA-DPB1 gene has been associated with granulomatosis with polyangiitis (GPA). This condition occurs when the immune system malfunctions and attacks the body’s own tissues and organs (autoimmunity), causing inflammation that affects the lungs, airways, and kidneys. The associated variant, called HLA-DPB1*0401, has been found more frequently in people with GPA than in those who do not have the condition; this variant is thought to increase the risk of developing GPA.

Because the HLA-DPB1 gene is involved in the immune system, changes in it might be related to the autoimmune response and inflammation that damage the lungs,
kidneys, and other organs. However, it is unclear what specific role the HLA-DPB1 gene variant plays in development of this condition. It is likely that environmental factors trigger the condition in people who are genetically predisposed to it. Other genetic factors are also likely to be involved in GPA.

**Juvenile idiopathic arthritis**

**Rheumatoid arthritis**

**Other disorders**

Variants of the HLA-DPB1 gene are associated with immune reactions to beryllium, a metallic element that can be toxic. Beryllium exposure can occur in manufacturing plants and the nuclear and aerospace industries. About 2 to 10 percent of people exposed to beryllium develop beryllium sensitization or chronic beryllium disease. Sensitization is an immune reaction that occurs in response to beryllium exposure; sensitization can cause an increase in the number of certain immune system cells in the blood, but it may not lead to any symptoms. In some people, sensitization leads to chronic beryllium disease, which is a lung disease characterized by the formation of small masses of inflammatory cells (granulomas). The lungs can become scarred and stiff and lose their ability to function. Having variants of the HLA-DPB1 gene that contain the protein building block (amino acid) glutamic acid at position 69 (written as E69) increases the risk of developing beryllium sensitization or chronic beryllium disease.

**Chromosomal Location**

Cytogenetic Location: 6p21.32, which is the short (p) arm of chromosome 6 at position 21.32

Molecular Location: base pairs 33,075,926 to 33,089,696 on chromosome 6 (Homo sapiens Annotation Release 109, GRCh38.p12) (NCBI)
